Objectives

- Describe adenocarcinoma of the stomach in terms of
  - etiology,
  - epidemiology,
  - signs and symptoms,
  - the risk factors for development of colorectal cancer.
- Outline the pathophysiologic development of colorectal cancer.
- Describe the following inheritable factors and syndromes for colorectal cancer:
  - Polyposis
  - Gardner's syndrome
  - Juvenile polyposis
- Describe the work-up and preventive measures for patients with familial polyposis.
- Discuss the clinical features and presenting signs and symptoms of colorectal cancer
- Summarize the Dukes classification of colorectal cancer and TNM classification and discuss the significance of staging.

- List and describe the factors that predict a poor outcome after total surgical resection for colorectal cancer
- Discuss the treatment of other colorectal tumors.
- Identify the symptoms that may indicate small bowel tumors, and discuss appropriate diagnostic imaging techniques and treatment
- Describe the following types of small bowel tumors
  - Adenomas
  - Polypoid adenomas
  - Leiomyomas
  - Lipomas
  - Angiomas
  - Carcinoid tumors

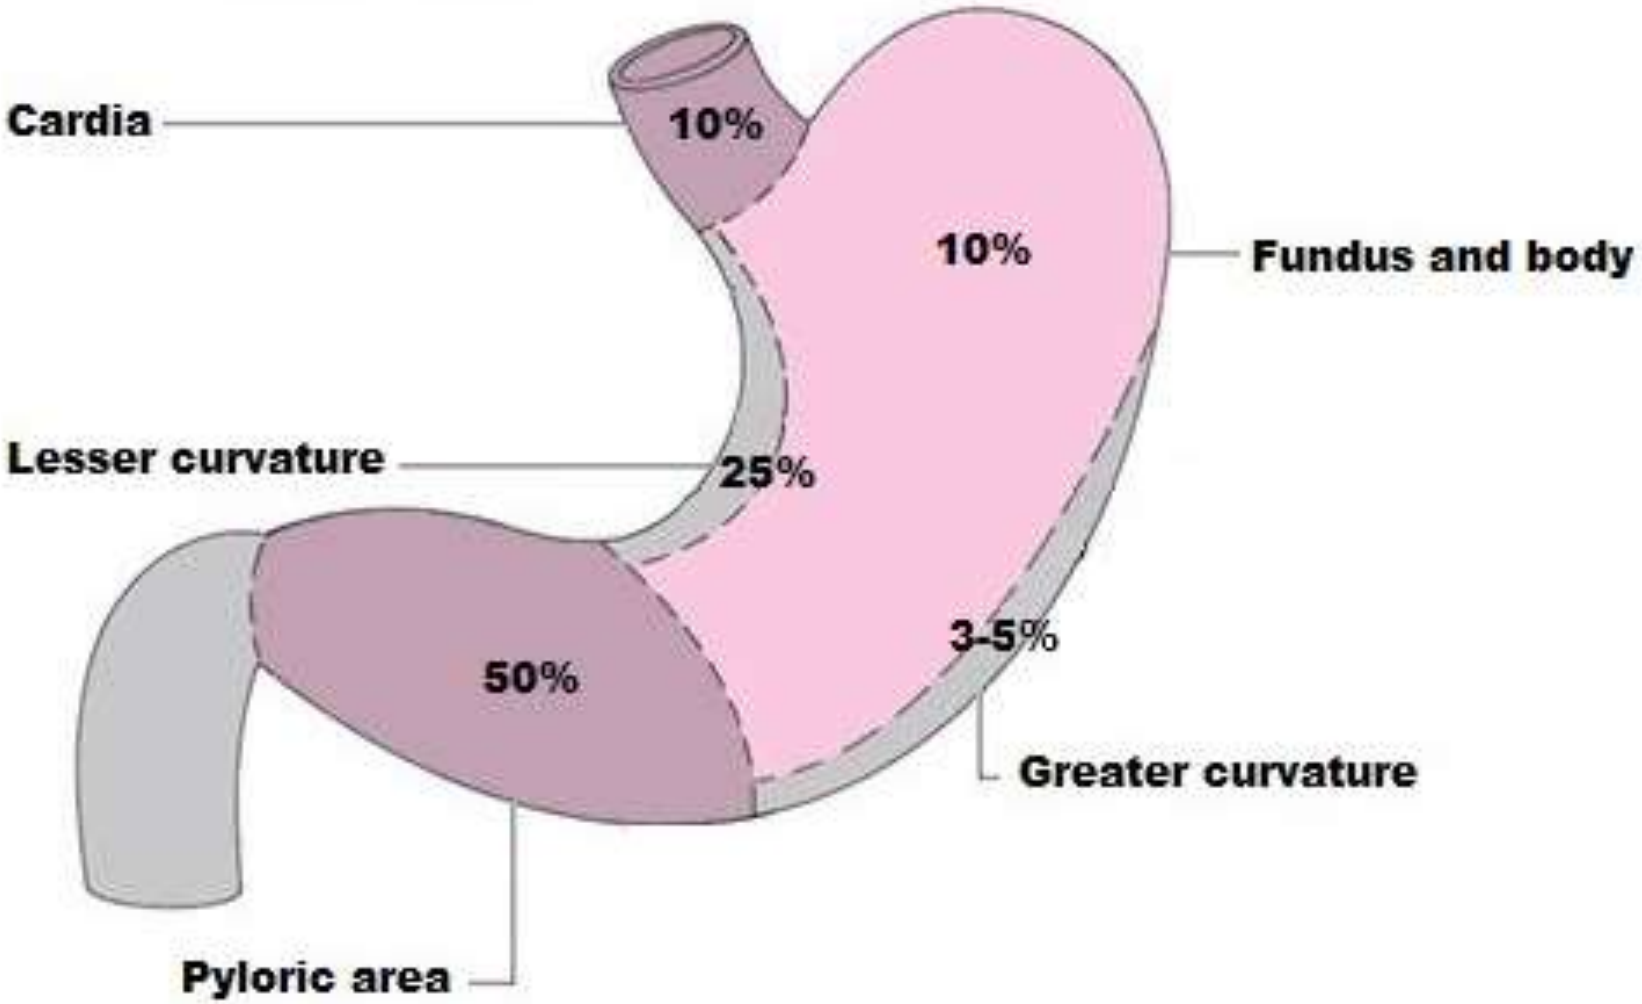
Locations of Stomach Cancer by Percentage



EPIDEMIOLOGY

- Rare before the age of 40,
  - Incidence steadily climbs thereafter
  - Peaks in the seventh decade of life.
- It is estimated that
  - 876,340 cases of primary gastric cancer
  - 650,000 deaths worldwide.

- In North America
  - The lifetime probabilities of developing and dying: 1.5% and 1.0%, respectively.
- Mortality rates
  - Females: 9.9 to 4.2 per 100,000
  - Males: 21.2 to 9.1 per 100,000
- In the United States
  - 24,000 new cases and 14,000 deaths annually.
  - 65% present at an advanced stage (T3/T4), with nearly 85%: node metastasis at diagnosis.

RISK FACTORS

ETHNIC FACTOR

- Incidence:
  - Highest in Japan
    >40 per 100,000, Eastern Asia, South America, and Eastern Europe
  - Lowest in canada
    10 per 100,000, Northern Europe, Africa, United States
- Ethnicity is identified into 3 groups:
  1. High
     Koreans, Vietnamese, Japanese, Native American, Hawaiian
  2. Intermediate
     Latino, Chinese, and black
  3. Low
     Filipino and white

RISK FACTOR

DIETARY FACTOR

- Rich in salt

  Leads to atrophic gastritis ---- Alteration in the gastric environment---- Generation of carcinogenic N-nitroso compounds.
- Rich in fruits and vegetables : reduced risk of cancer.
- Raw vegetables and fruit: decreased the risk of gastric cancer
- Calcium, vitamin A, and vitamin C: protective effect on the gastric mucosa----- through the reduced formation of N-nitroso carcinogenic compounds.

BEHAVIORAL FACTORS

- Cigarette smokers: 2- 3 times increased risk of proximal gastric cancer.
- Smoked or poorly preserved foods,
- Habitual alcohol consumption.

RISK FACTOR

NON-GENETIC

- Sporadically,

GENETIC : inherited familial component

- 8% to 10%:
  - Germline mutations in p53 (Li-Fraumeni syndrome)
  - BRCA2
- In 1% to 3%
  - Germline mutations in the gene encoding the cell adhesion protein E-cadherin--- leads to an autosomal-dominant
  - Hereditary diffuse gastric cancer
  - Should prompt prophylactic gastrectomy in affected kindreds.
- Hereditary nonpolyposis colon cancer (HNPCC) syndrome
- Gastrointestinal polyposis syndromes,
  - Familial adenomatous polyposis (FAP) and Peutz-Jeghers syndrome.

RISK FACTOR

INFECTION-INFLAMATION

- *Helicobacter pylori* infection.
  - 10 or more years before the cancer diagnosis
  - Induce changes in the gastric mucosa and the gastric flora
  - Capable of adhering to the Lewis blood group antigen---important factor facilitating chronic infection--- increased cancer risk in blood group A phenotype.
- Chronic atrophic gastritis
  - Pernicious anemia

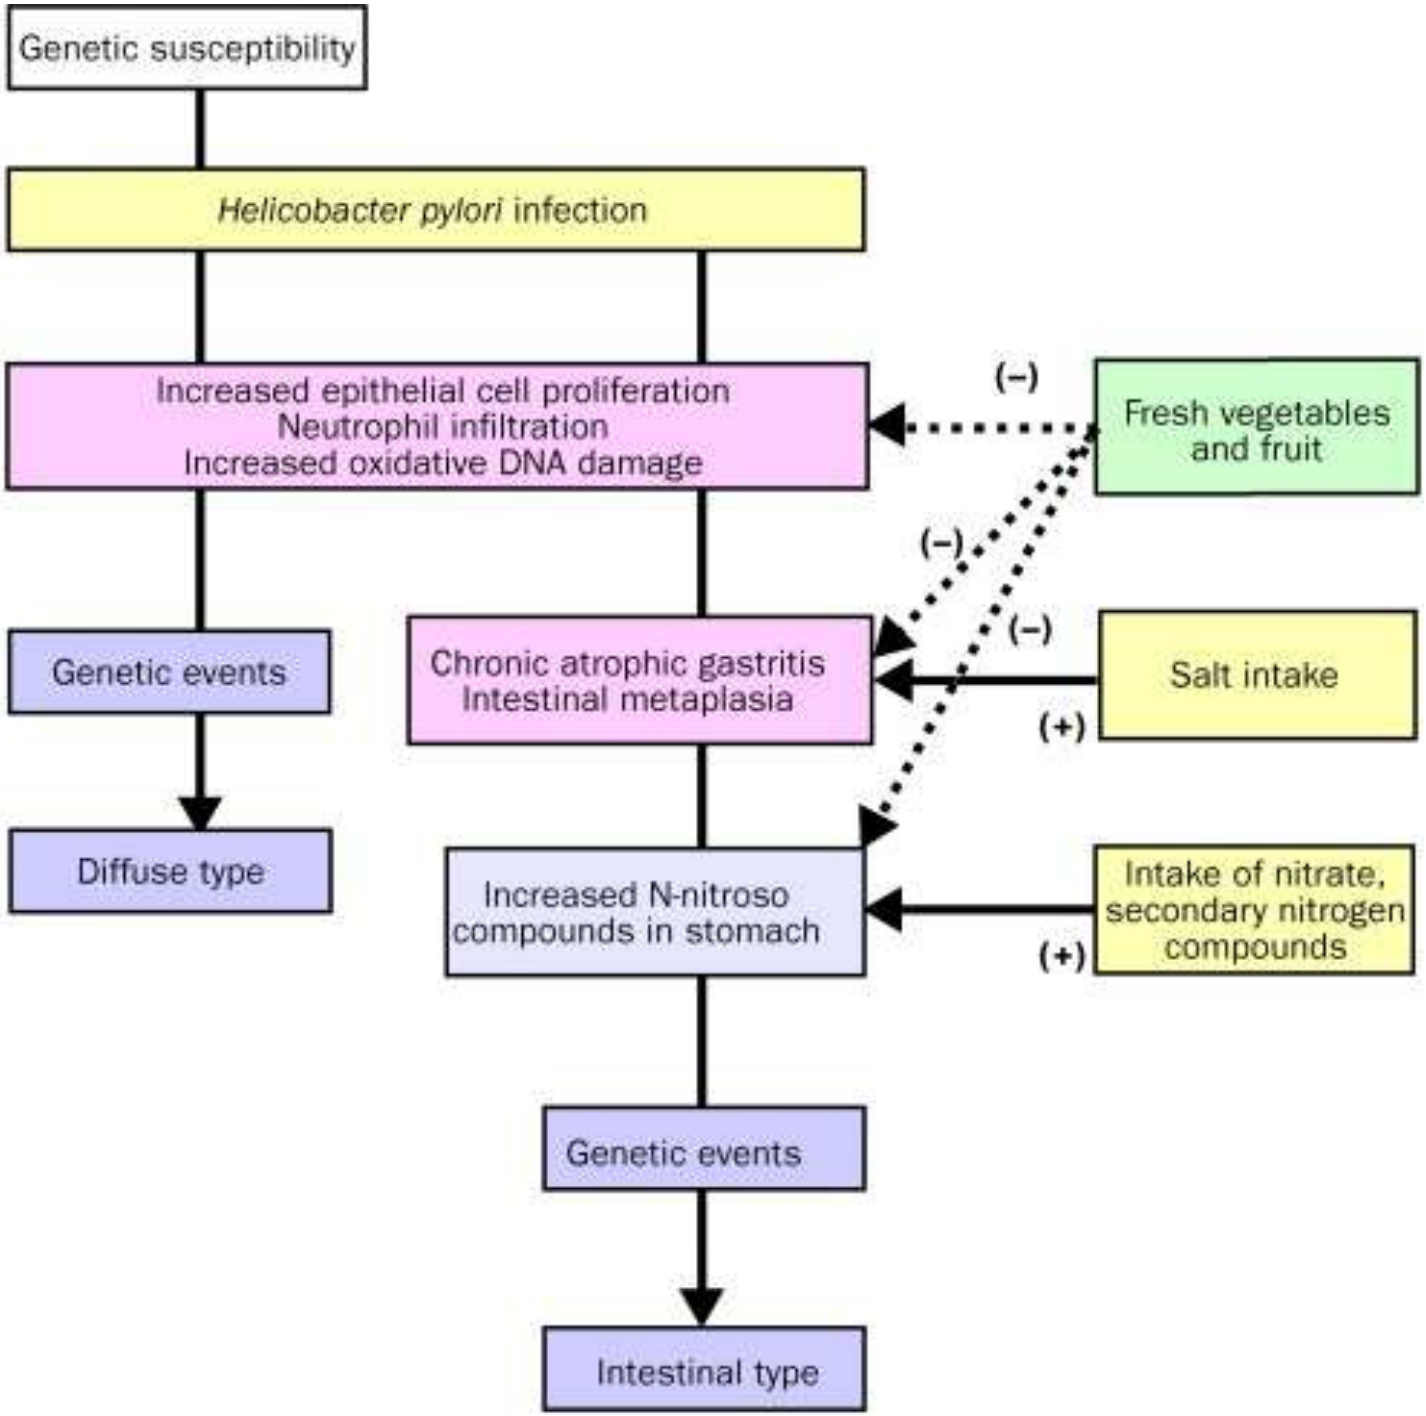
OTHERS

- Previous gastric surgery with bile reflux,
- Hypertrophic gastropathy (Metenier's disease),
- Gastric polyps,
- Obesity.

H.PYLORI-AUTOIMMUNE GASTRITIS

- Create an environment conducive to gastric inflammation.
  - Gastritis persists
  - Gastric atrophy------ Intestinal metaplasia--- lead to dysplasia.
- Dysplasia can arise in either
  - the native gastric or
  - “intestinalized” gastric epithelium

.



Genetic susceptibility

Intestinal type

CLASSIFICATION

The 2 most commonly used are

1. Lauren System
2. WHO Systems

This system describes tumors on the basis of microscopic configuration and growth pattern.

LAUREN SYSTEM

- The Lauren classification divides gastric cancer into 2 major histologic types:
  1. Diffuse
  2. Intestinal
- Useful in evaluating the natural history of gastric carcinoma, especially with regard to
  - Incidence trends,
  - Clinicopathologic correlations
  - Etiologic precursors.

Intestinal type
Mixed type
Diffuse type

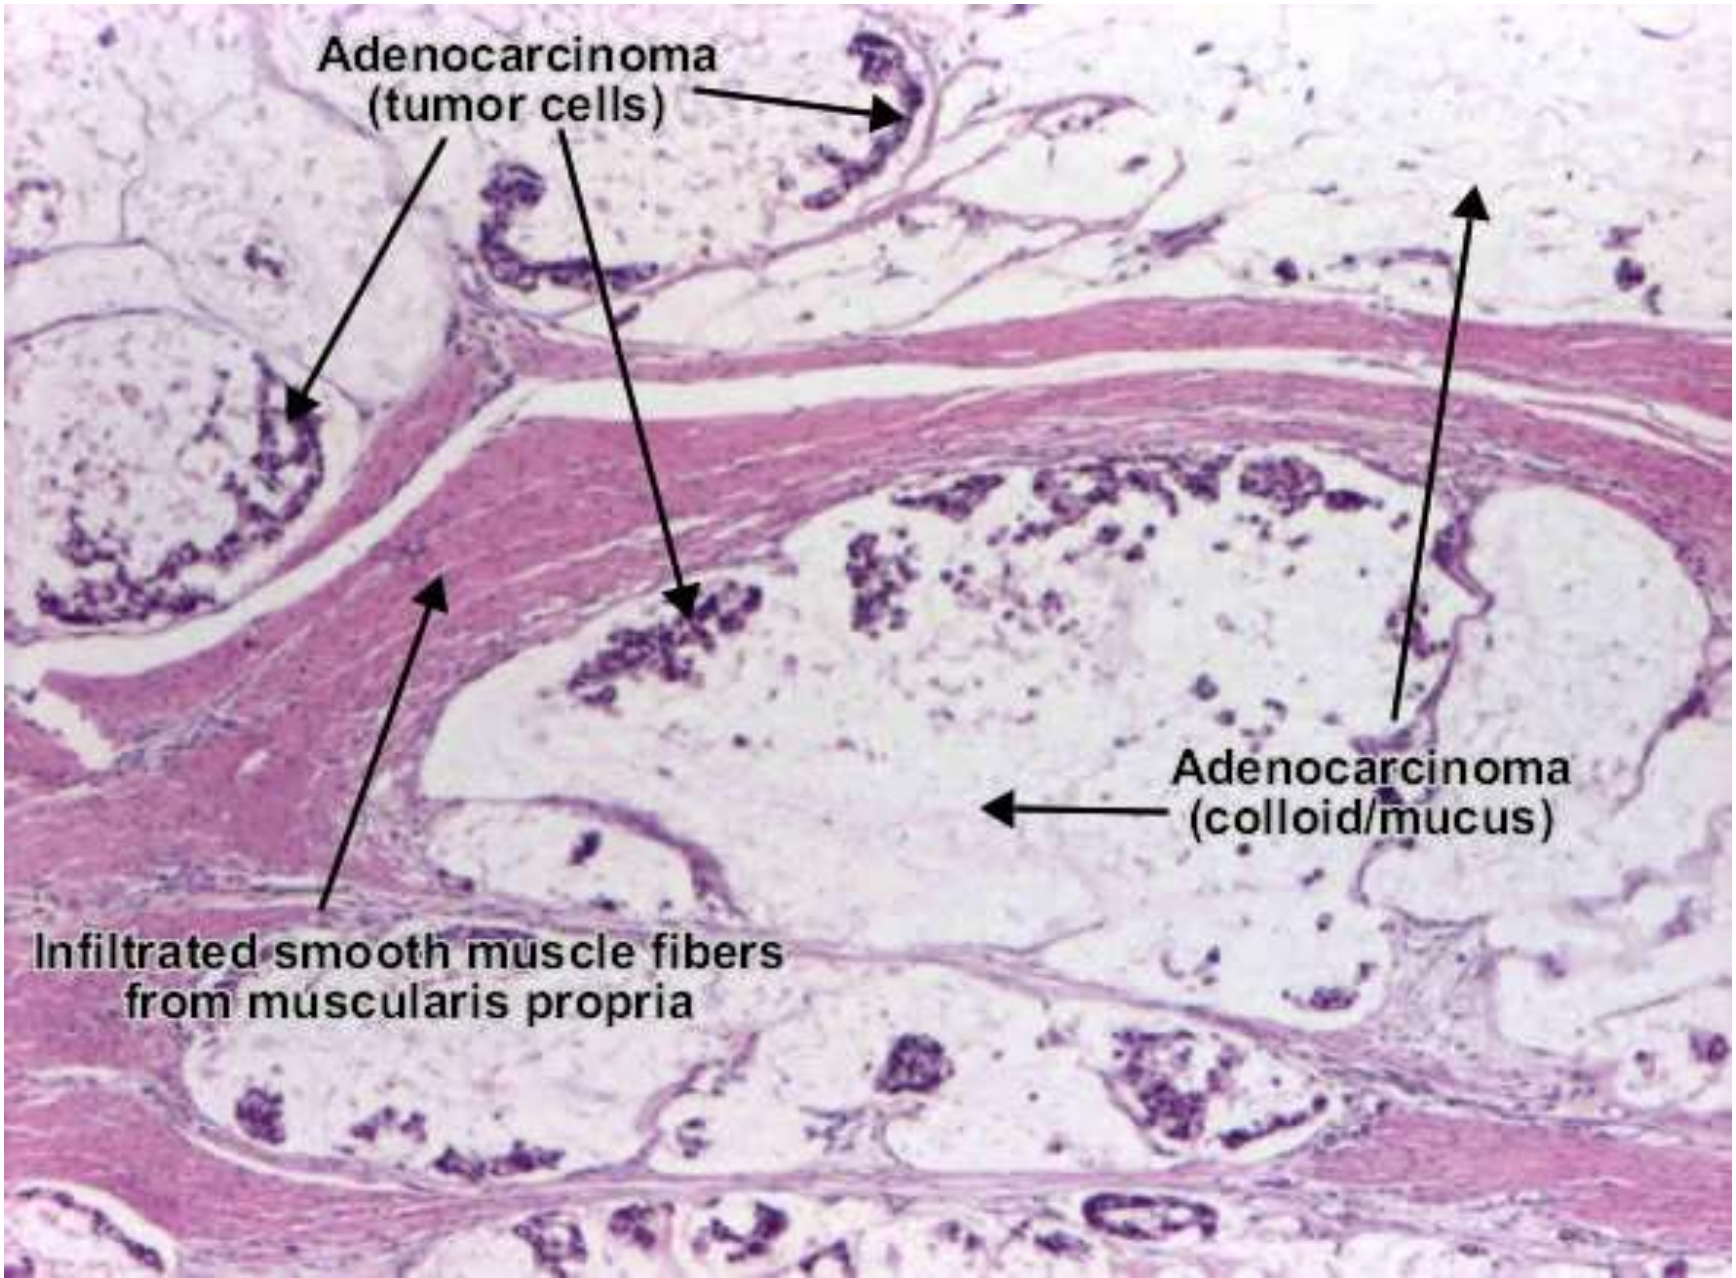
WHO SYSTEM

- Has revised the definition:

  "malignant epithelial tumors of the gastric mucosa with glandular differentiation.
- Based on the degree of resemblance to metaplastic intestinal tissue.
- Histologic patterns into 5 subtypes:
  1. Adenocarcinoma (intestinal and diffuse),
  2. Papillary
  3. Tubular
  4. Mucinous
  5. Signet-ring cell.

DIFFUSE-TYPE CANCER

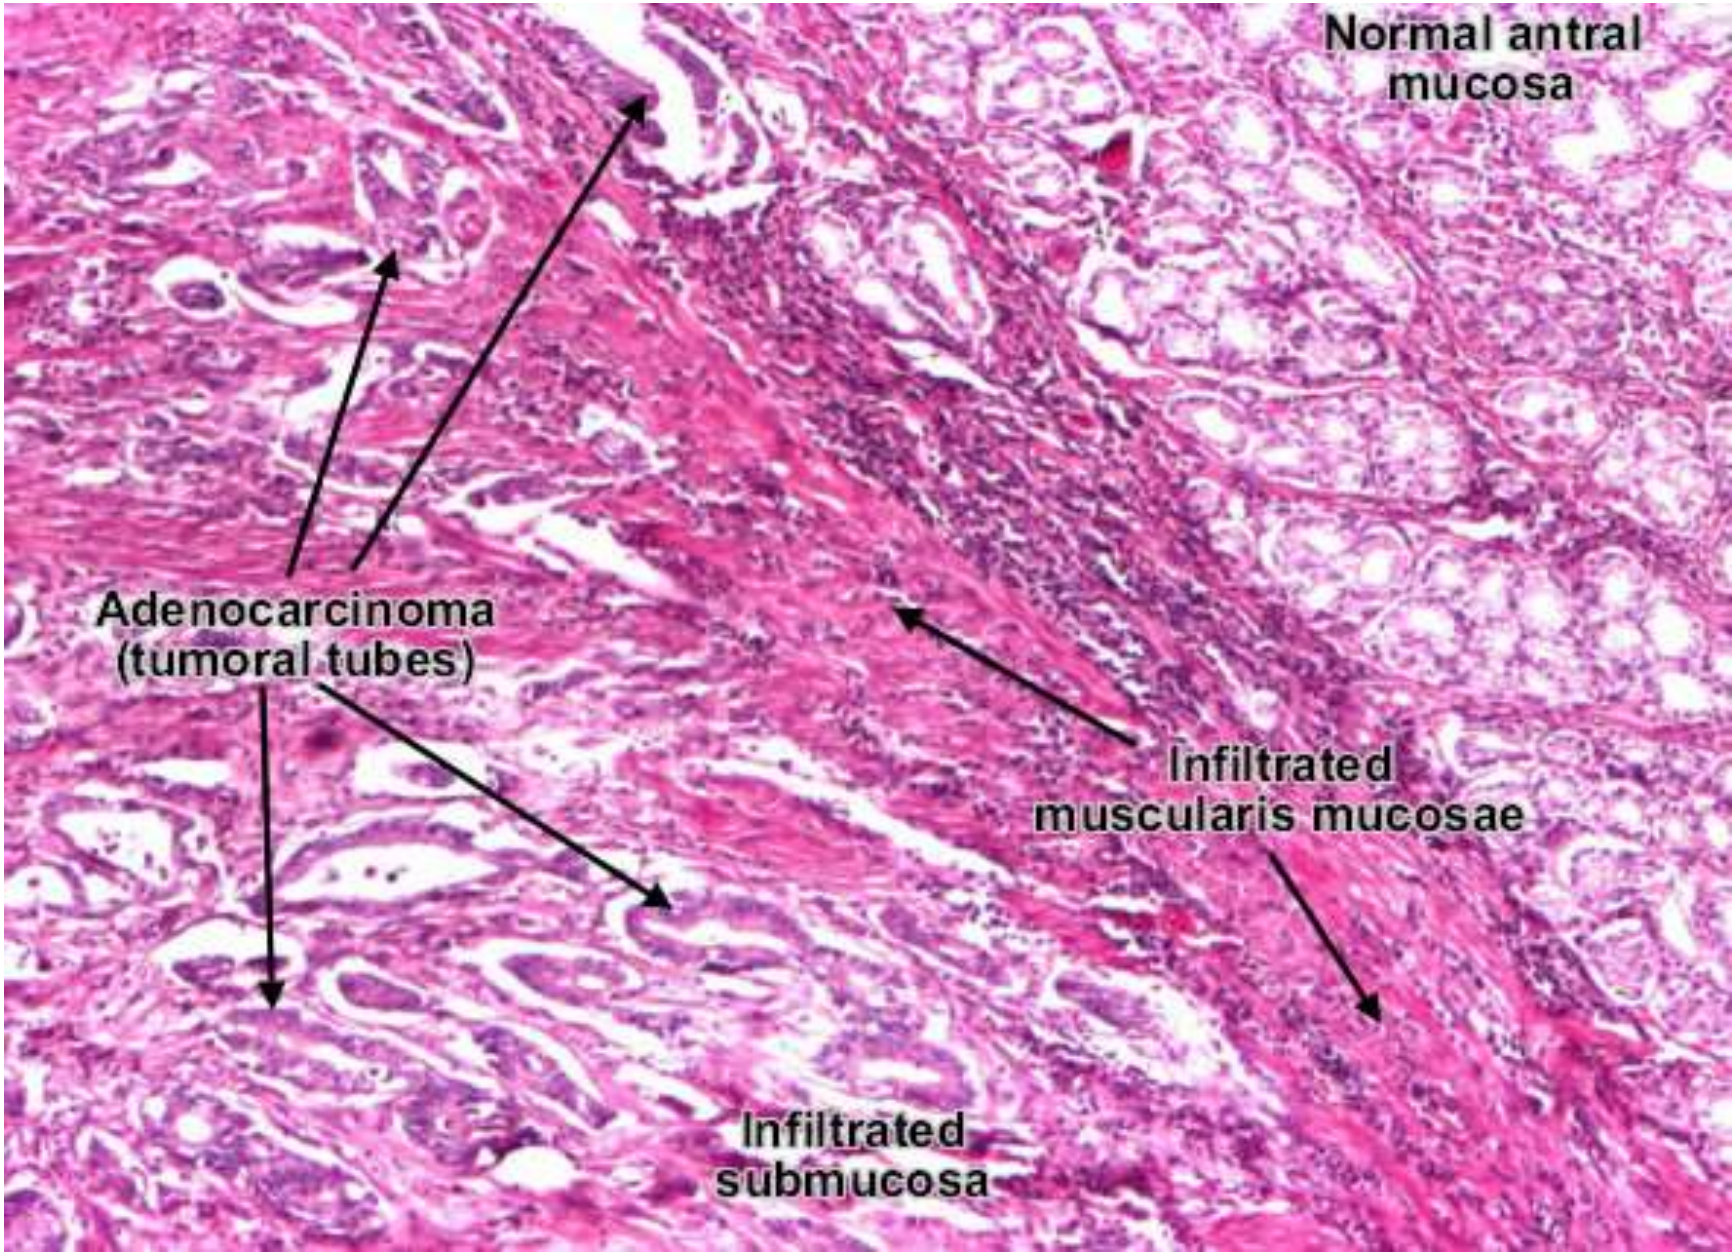
- Noncohesive tumor cells diffusely infiltrating the stroma of the stomach
  - Deep infiltration of the stomach wall with little or no gland formation.
- Desmoplasia
- Associated inflammation
- More often in young
- Worse prognosis
- Not associated with intestinal metaplasia
- Not localized to the antrum
- Single-cell mutations within normal gastric glands--hereditary diffuse gastric carcinoma



Adenocarcinoma
(tumor cells)
Adenocarcinoma
(colloid/mucus)
Infiltrated smooth muscle fibers
from muscularis propria

INTESTINAL TYPE CANCER

- Recognizable gland formation similar in microscopic appearance to colonic mucosa.
- Glandular formation ranges from well to poorly differentiated tumors
- Grow in expanding, rather than infiltrative
- Secondary to chronic atrophic gastritis.



Normal antral mucosa
Adenocarcinoma (tumoral tubes)
Infiltrated muscularis mucosae
Infiltrated submucosa

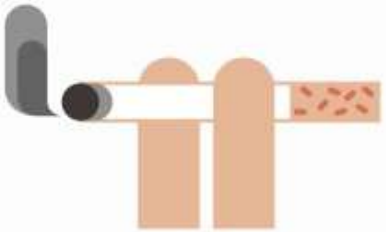
ADENOMA

- Dysplastic proliferation produces a macroscopic protruding lesion and as tubular, tubulovillous, or villous adenoma morphologically.
- In the distal stomach
- Prolonged precancerous phase---expanding growth pattern.
- Carcinoma is diagnosed when the tumor invades into the lamina propria or through the muscularis mucosae.
- Up to 80% of dysplastic lesions may progress to invasion

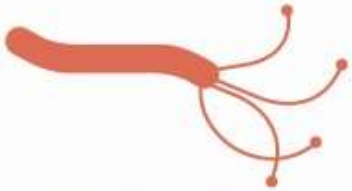
STOMACH CANCER

RISK FACTORS

LONG- TERM INFLAMMATION OF THE STOMACH



SMOKING



HELICOBACTER PYLORI INFECTION

FAMILY HISTORY

POOR DIET OR OBESITY

SYMPTOMS

PAIN IN THE STOMACH AREA

DIFFICULTY SWALLOWING

WEIGHTLOSS

BLOATED AFTER A SMALL MEAL

NAUSEA AND VOMITING

VOMITING BLOOD OR HAVING BLOOD IN THE STOOL

CLINICAL MANIFESTATIONS

Symptoms

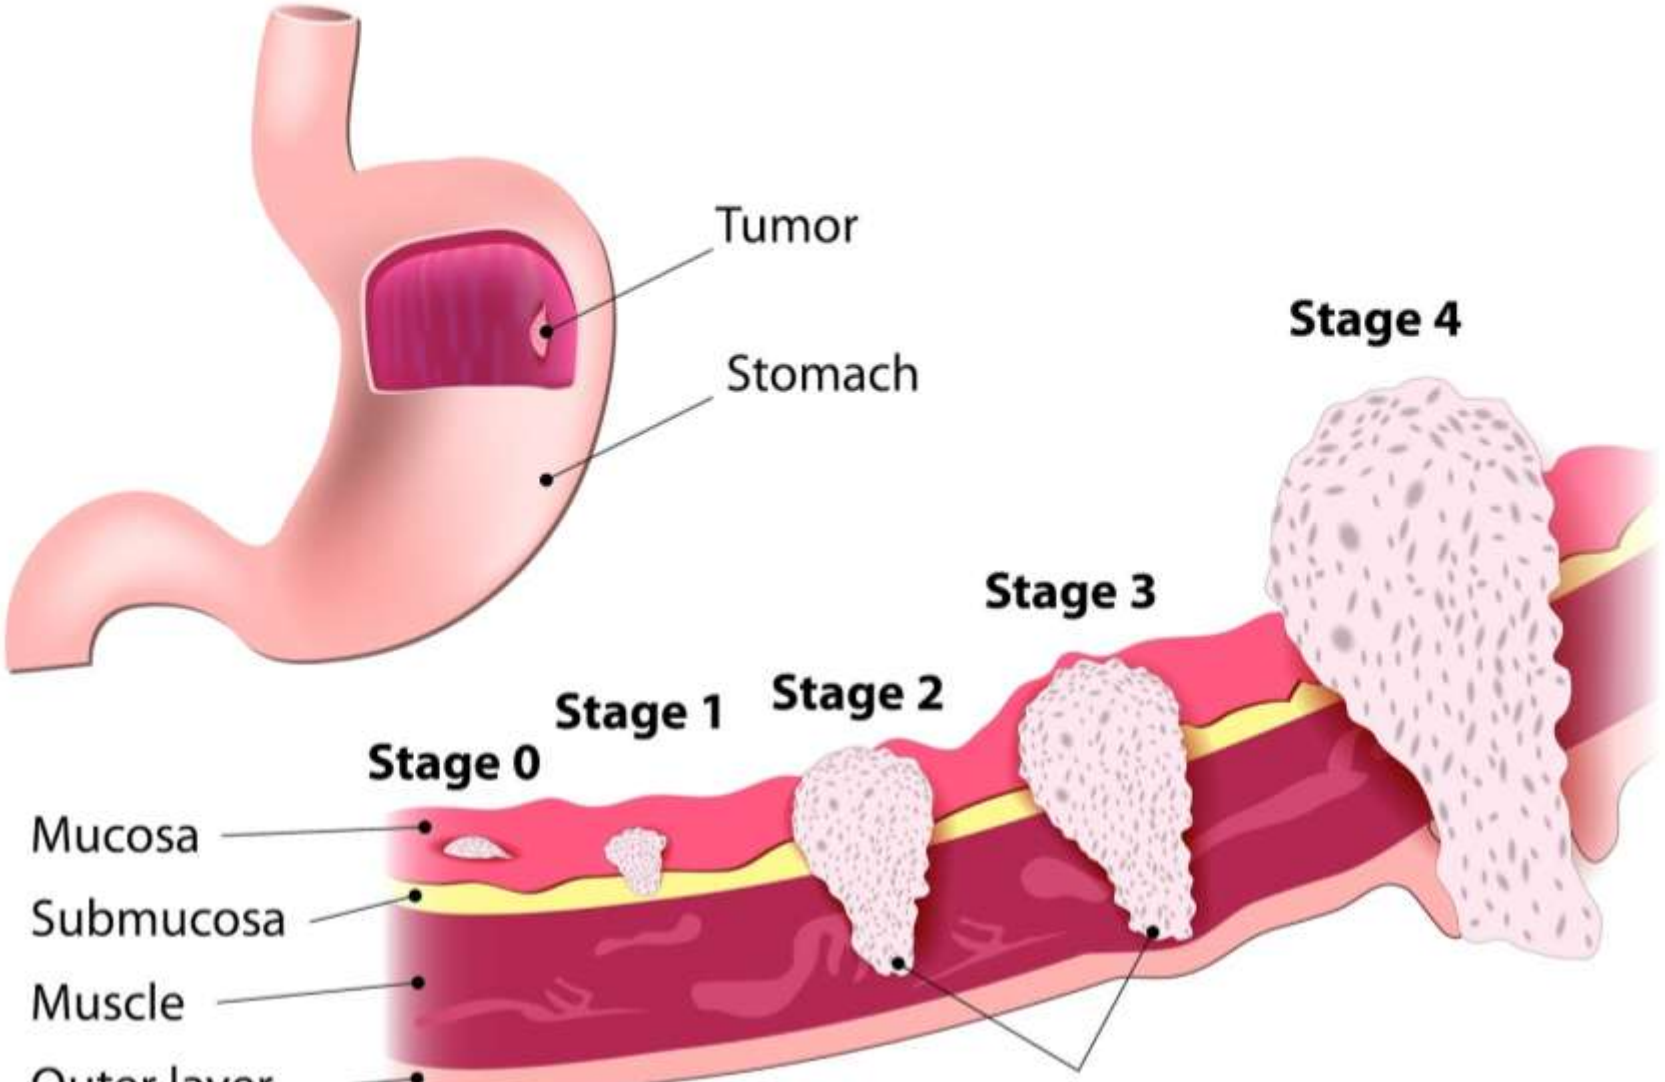
- No specific symptoms when it is superficial
  - Up to 50% of patients: Nonspecific gastrointestinal complaints-- Dyspepsia
- Often delays the diagnosis-- 80% to 90%: advanced or metastatic tumors
- Anorexia and weight loss (95%) as well as abdominal pain that is vague and insidious in nature.
- Nausea, vomiting, and early satiety
  - Occur with bulky tumors that obstruct the gastrointestinal lumen or infiltrative lesions that impair stomach distension.
- Ulcerated tumors may cause bleeding: hematemesis, melena, or massive upper gastrointestinal hemorrhage.

CLINICAL MANIFESTATIONS

Physical examination

- Usually uninformative (in early)
- Advanced tumors may present with
  - Palpable abdominal mass
  - Cachexia,
  - Bowel obstruction
  - Ascites
  - Hepatomegaly
  - Lower extremity edema
- Peritoneal seeding may cause involvement of
  - Ovaries (Krukenberg tumor)
  - Pelvic cul de sac (Blumer's shelf) detectable on rectal examination
- Metastasis may manifest as
  - Enlarged supraclavicular lymph node (Virchow's node),
  - Left axillary lymph node (Irish's node), or
  - Periumbilical lymph node (Sister Mary-Joseph's node)

STAGES OF STOMACH CANCER



Gastric Cancer Survival by stage

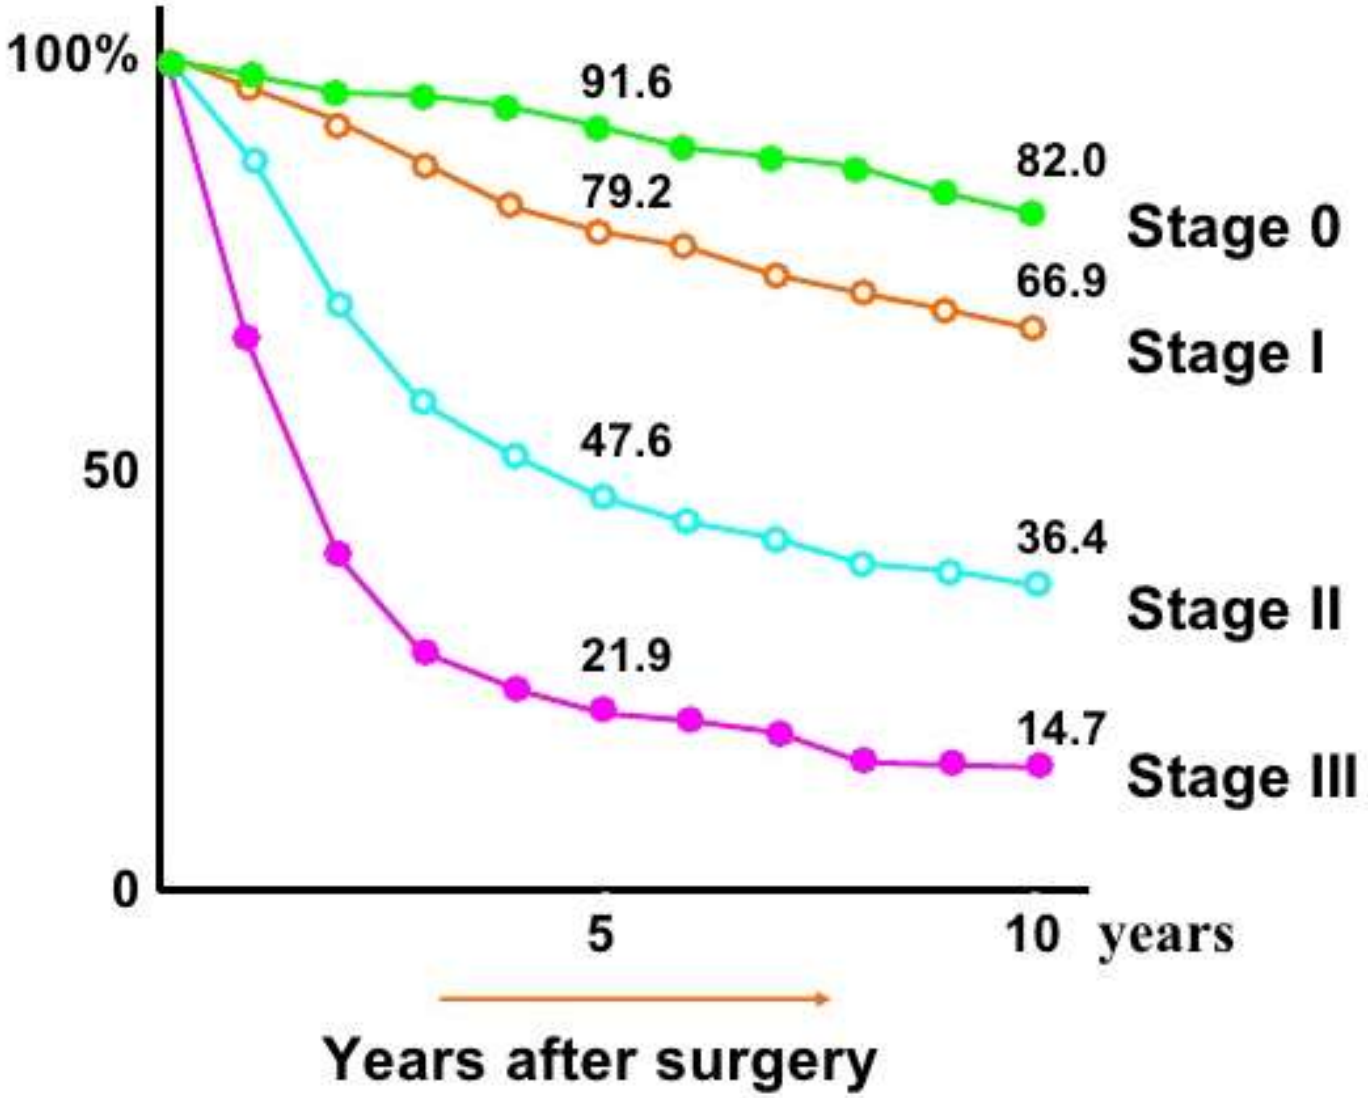


TABLE 1. Japanese Classification for Gastric Carcinoma (JCGC)

Lymph Node Group	Anatomic Location	D Categor
Group 1	Left cardiac, right cardiac, greater and lesser curvature supra- and infrapyloric	D1
Group 2	Left gastric, common hepatic, splenic artery, splenic hilum hepatic proper, celiac	D2
Group 3	Lepatoduodenal, posterior pancreas, root of mesentery, paraesophageal, diaphragmatic	D3

D indicates extent of surgical resection according to Western nomencla ture; D1, group 1; D2, groups 1 + 2; D3, groups 1+ 2 + 3 + paraaorti dissection.

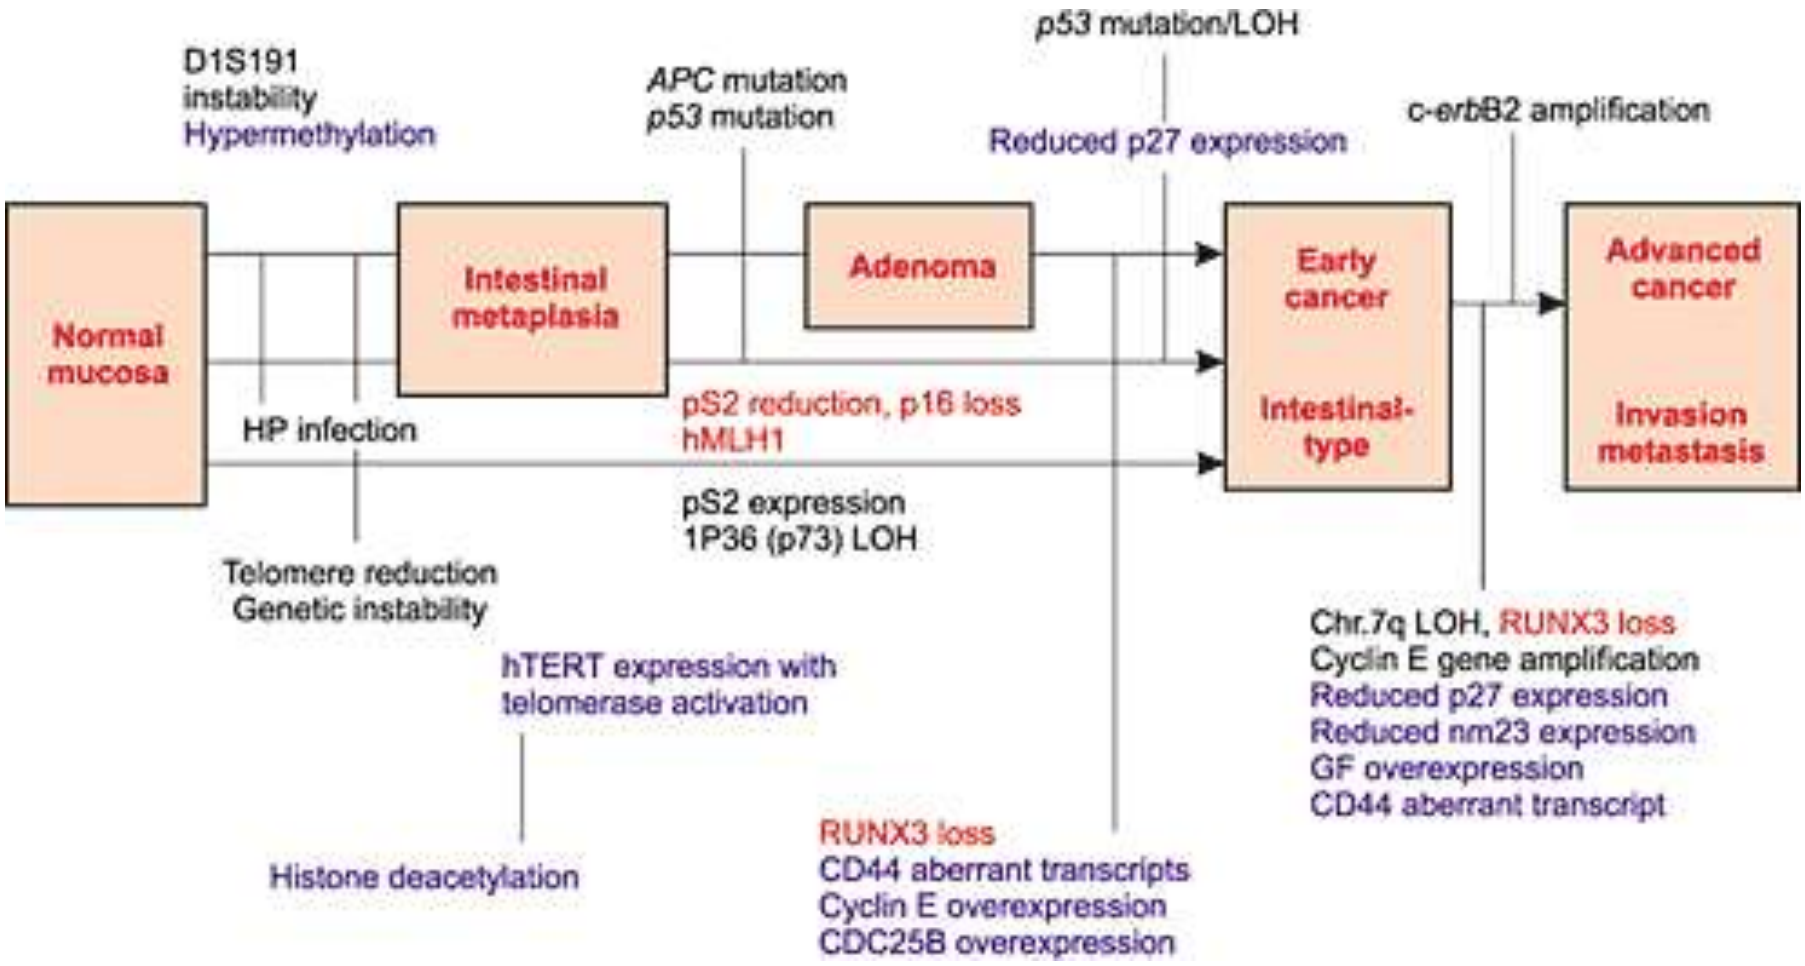
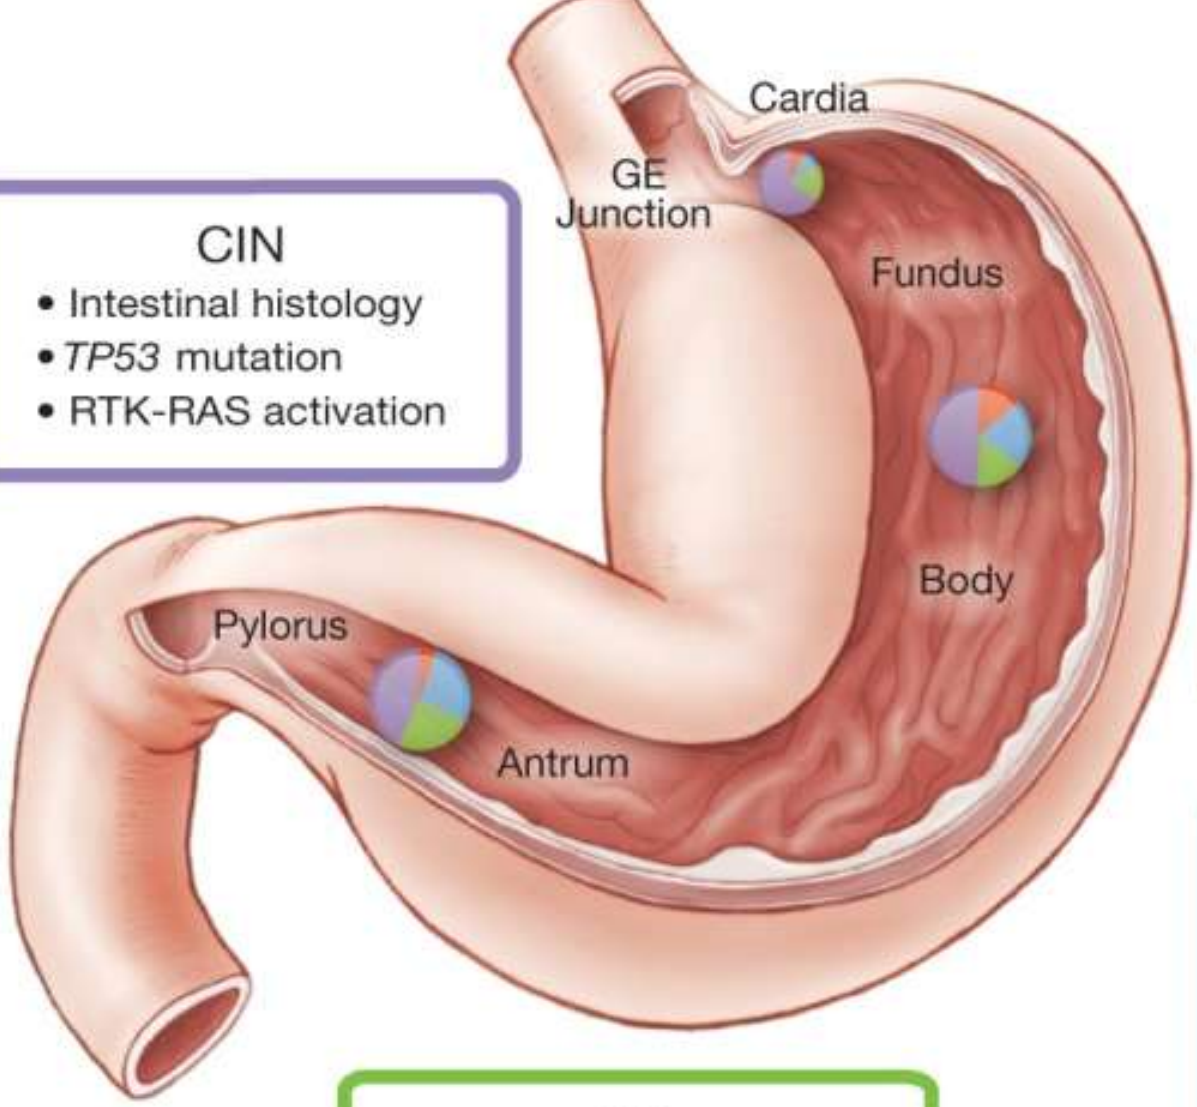
MOLECULER OF CANCER





CIN

- Intestinal histology
- *TP53* mutation
- RTK-RAS activation

EBV

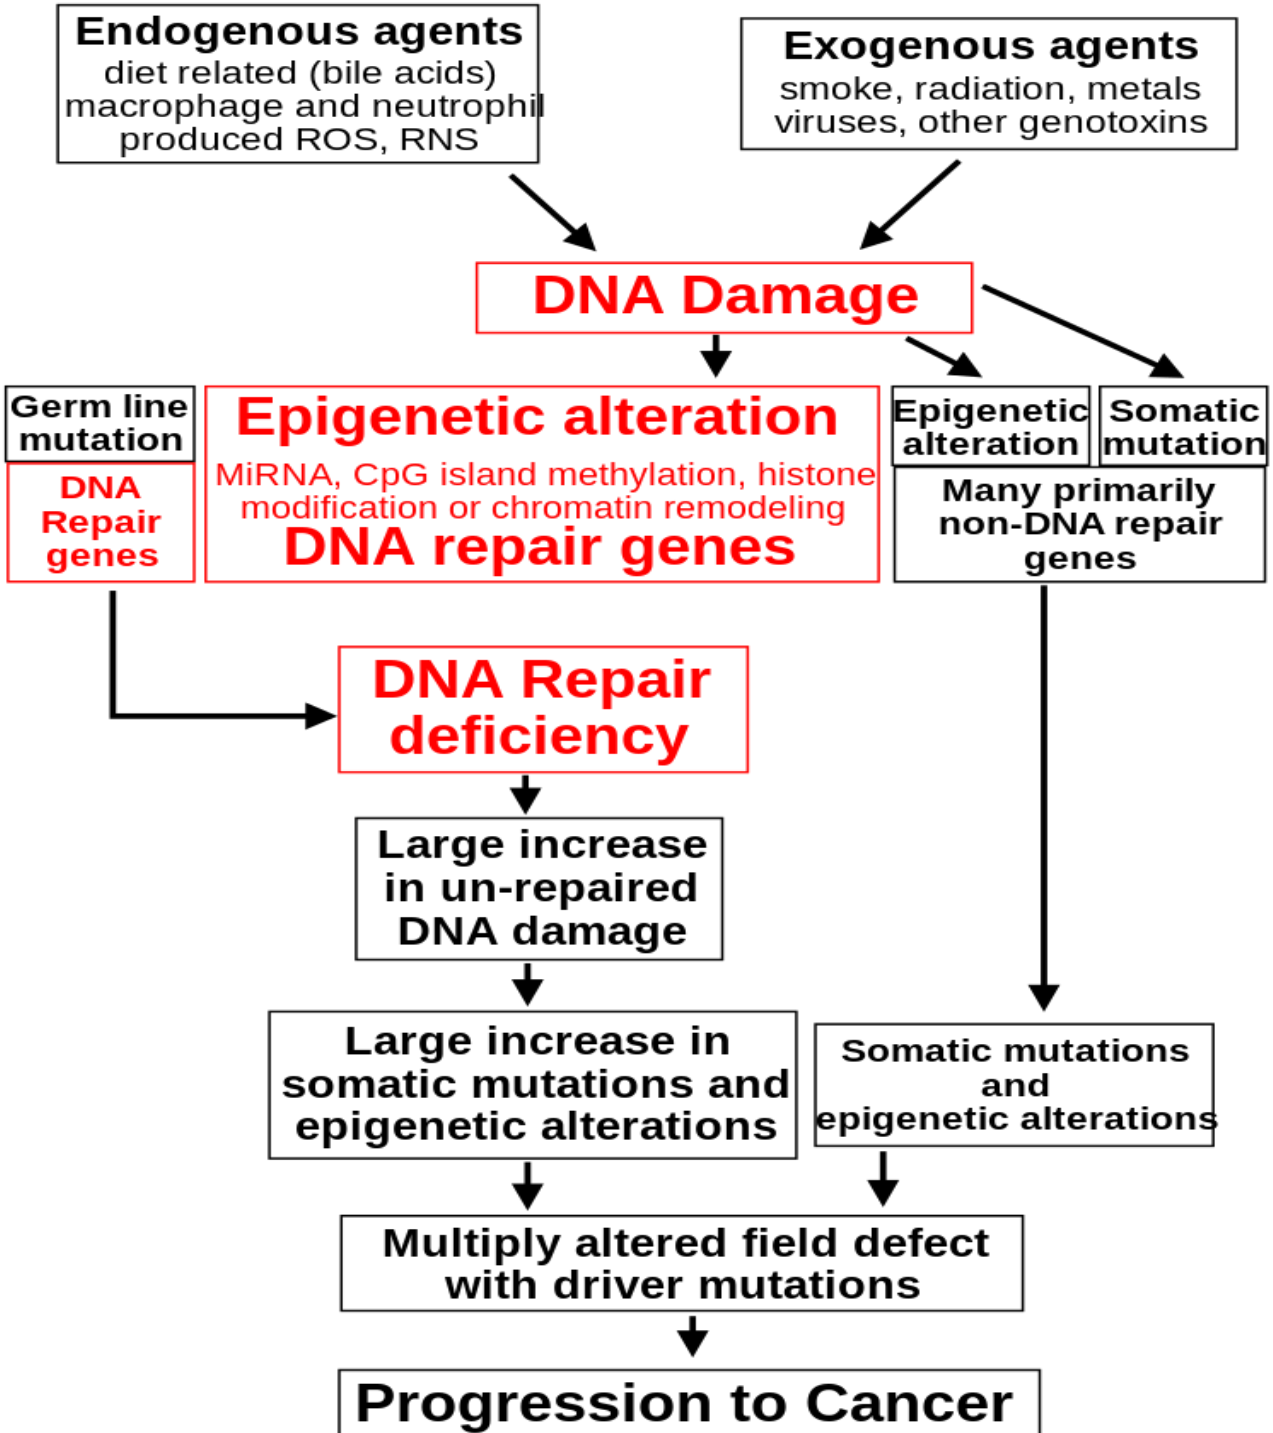
- *PIK3CA* mutation
- *PD-L1/2* overexpression
- EBV-CIMP
- *CDKN2A* silencing
- Immune cell signalling

MSI

- Hypermutation
- Gastric-CIMP
- *MLH1* silencing
- Mitotic pathways

GS

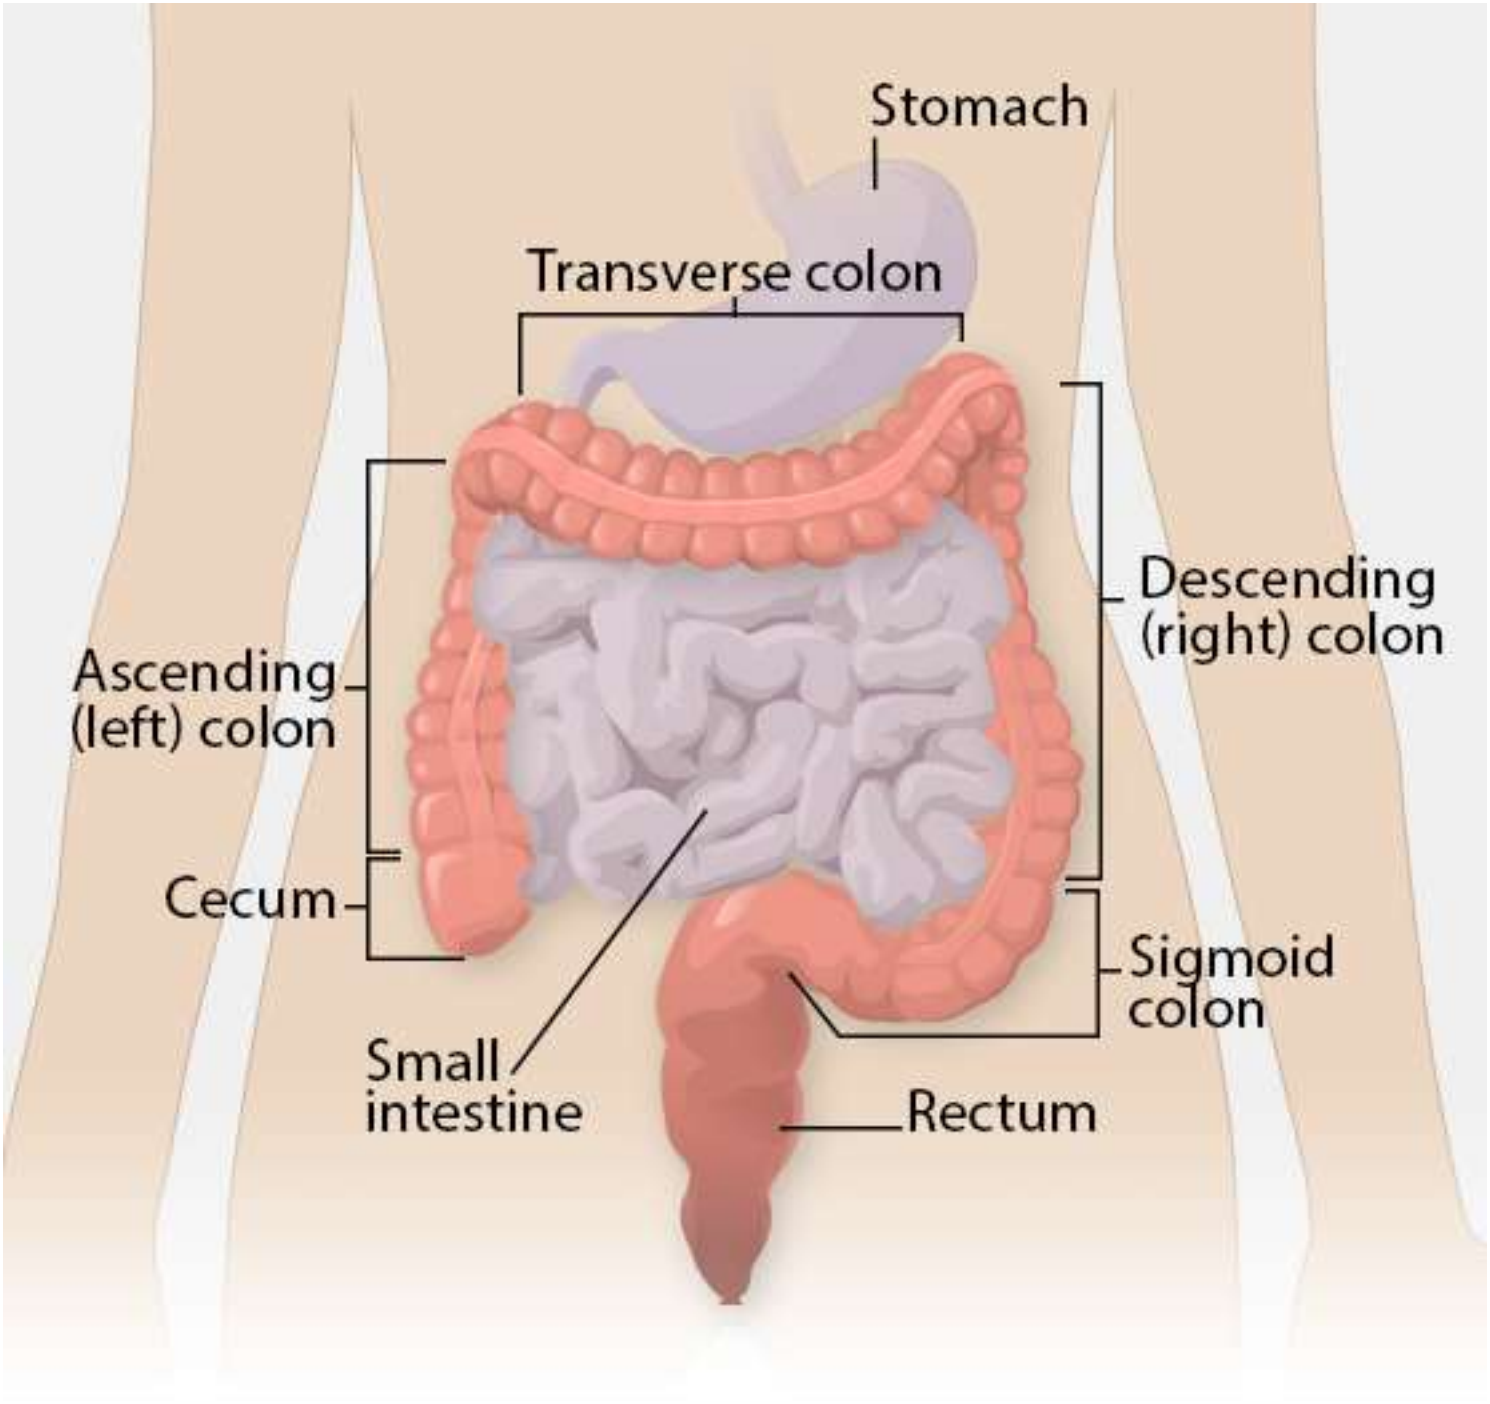
- Diffuse histology
- *CDH1*, *RHOA* mutations
- *CLDN18–ARHGAP* fusion
- Cell adhesion



Endogenous agents
diet related (bile acids)
macrophage and neutrophil
produced ROS, RNS
Exogenous agents
smoke, radiation, metals
viruses, other genotoxins
DNA Damage
Germ line mutation
DNA Repair genes
Epigenetic alteration
MiRNA, CpG island methylation, histone modification or chromatin remodeling
DNA repair genes
Epigenetic alteration
Somatic mutation
Many primarily non-DNA repair genes
DNA Repair deficiency
Large increase in un-repaired DNA damage
Large increase in somatic mutations and epigenetic alterations
Somatic mutations and epigenetic alterations
Multiply altered field defect with driver mutations
Progression to Cancer

COLORECTAL CANCER

- Cancer that starts in the colon or the rectum.
- Colon cancer or rectal cancer, depending on where they start.
- Grouped together because they have many features in common.
- Most colorectal cancers begin as a growth on the inner lining of the colon or rectum called a *polyp*.
- Some types of polyps can change into cancer over the course of several years, but not all polyps become cancer.
- The chance of changing into a cancer depends on the kind of polyp.



Stomach
Transverse colon
Descending (right) colon
Ascending (left) colon
Cecum
Sigmoid colon
Small intestine
Rectum

YOU ARE AT RISK IF :-

Diet high in red meat and low fiber

Over weight

Smoking

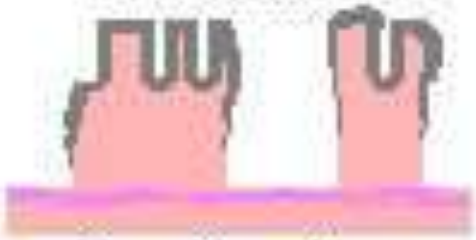
adenoma

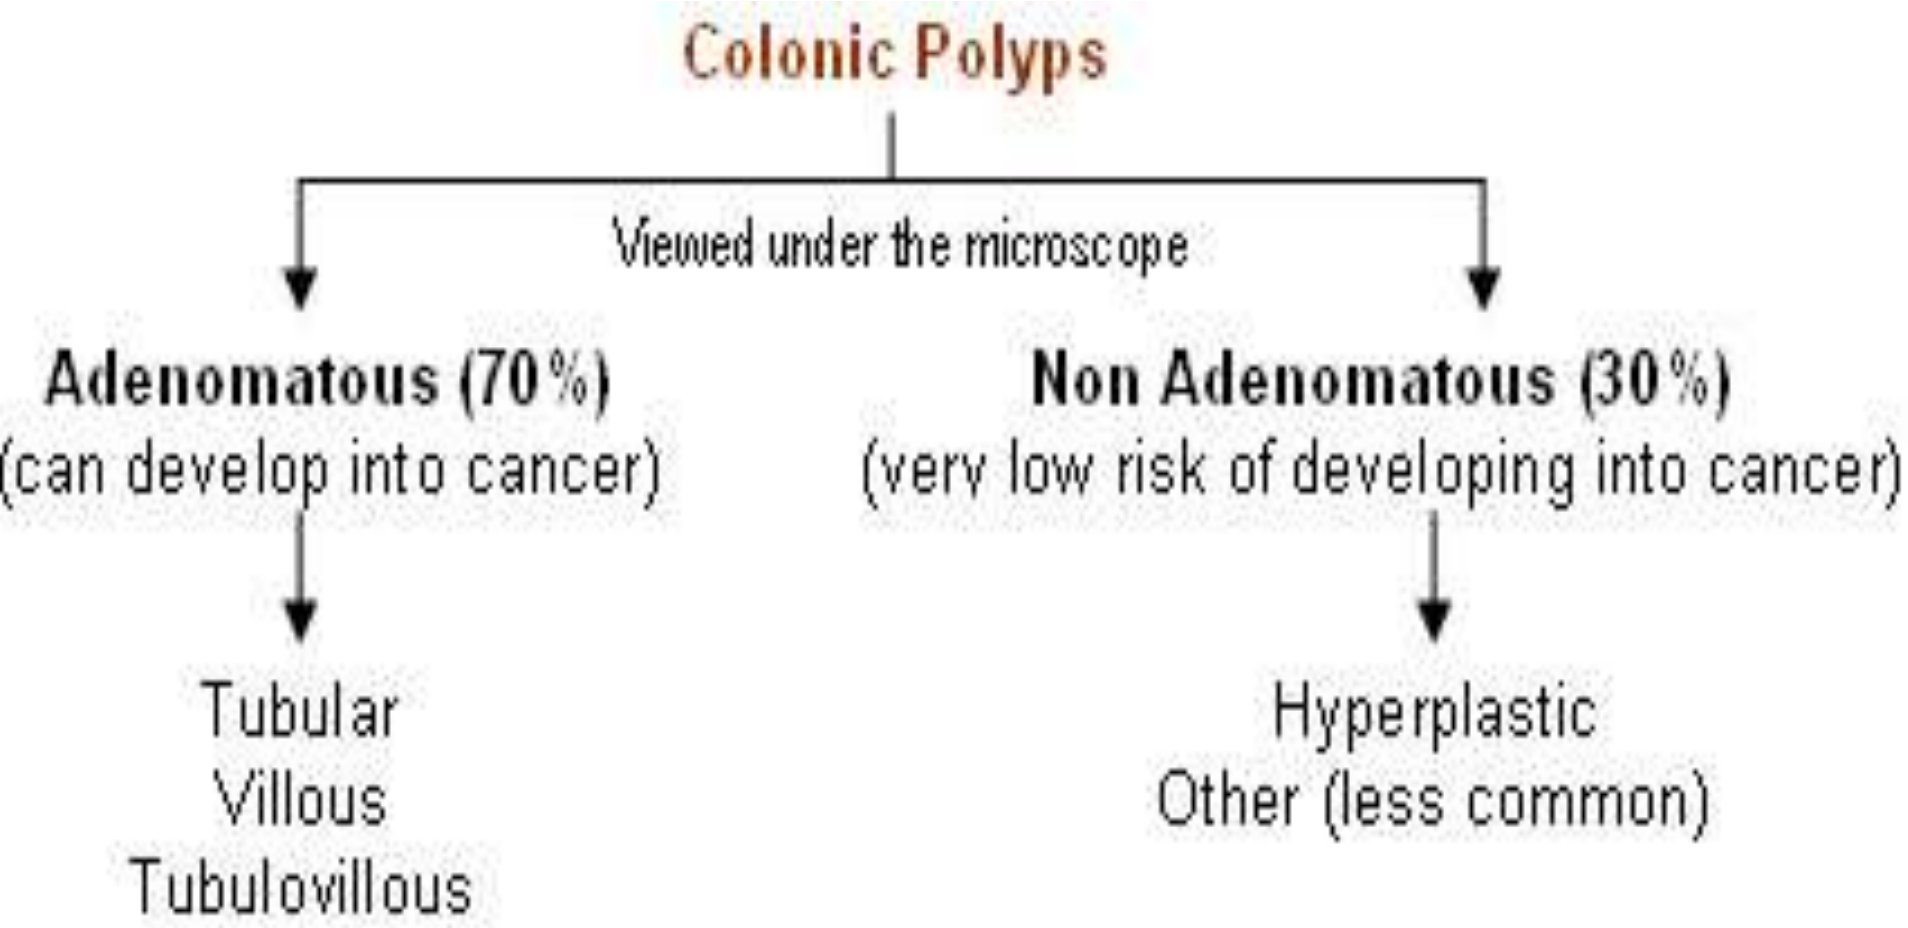


Pseudopolyps

Adenocarcinoma

HISTOLOGIC CLASSIFICATION OF POLYPS

- Adenomas are one histologic subtype of colorectal polyps.
- Other histologic subtypes include mucosal polyps, hyperplastic/ serrated polyps, juvenile polyps, and inflammatory polyps.
- In addition, certain types of polyps can arise from layers deeper than the mucosa, including lipomas, carcinoid tumors, gastrointestinal stromal tumors (GIST), and serosal lesions.



Colonic Polyps
Viewed under the microscope
Adenomatous (70%)
(can develop into cancer)
Non Adenomatous (30%)
(very low risk of developing into cancer)
Tubular
Villous
Tubulovillous
Hyperplastic
